

## Objective

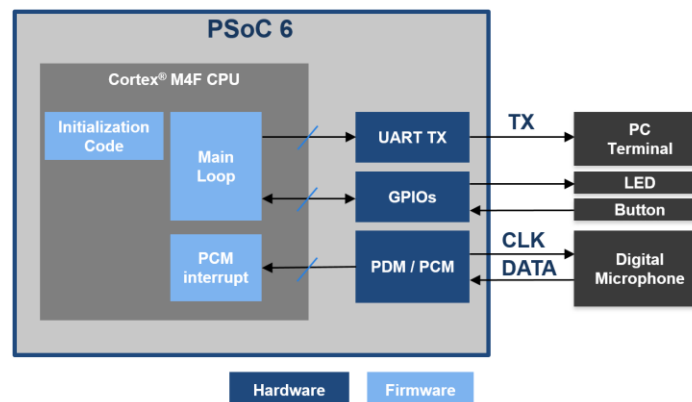

This example demonstrates how to use the pulse-density modulation/pulse-code modulation (PDM/PCM) hardware block in PSoC 6 with a digital microphone.

## Overview

This code example shows how to use a digital microphone with the PDM/PCM block. It measures the sound intensity (volume), and turns ON an LED when the volume exceeds a threshold. You can reset the threshold by pressing a switch; you can use this to capture the environment noise and set a new threshold above the noise. A debug UART reports the current volume.

Figure 1 shows the high-level block diagram of the interface between PSoC 6 and the microphone and user interface elements.

Figure 1. Block Diagram

## Requirements

**Tool:** PSoC® Creator™ 4.2

**Programming Language:** C (ARM® GCC 5.4-2016-q2-update)

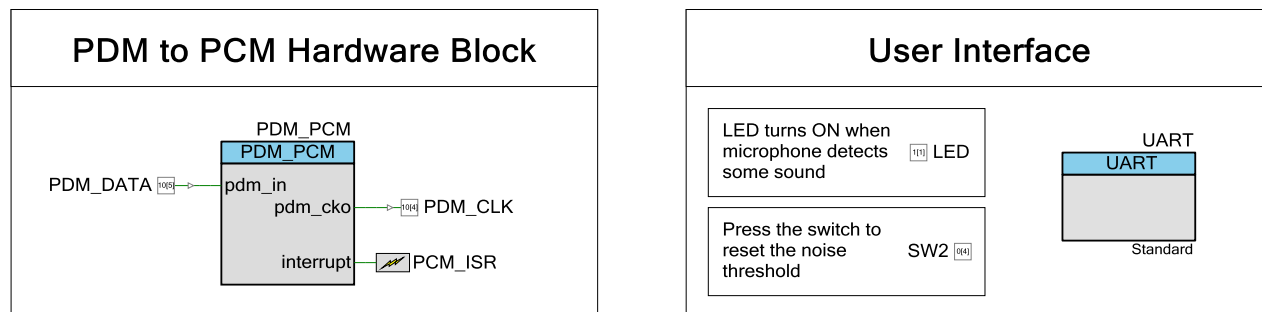

**Associated Parts:** All PSoC 6 parts with the PDM/PCM hardware block

**Related Hardware:** CY8CKIT-062 or CY8CKIT-062-BLE, CY8CKIT-028-EPD

## Design

Figure 2 shows the PSoC Creator schematic for interfacing a digital microphone with the PDM\_PCM Component.

Figure 2. Project Schematics

The CY8CKIT-028-EPD shield has a microphone with a single-bit PDM output. This allows you to convert any audio captured by the microphone into a digital signal (PDM). The PSoC 6 device in CY8CKIT-062 converts this digital signal to a quantized 16-bit value (PCM). An interrupt is triggered when there is enough data to be processed (at least 128 samples). The absolute values of the samples are summed and divided by the number of samples. This represents the overall loudness of the sound, which is proportional to the volume.

The PDM\_CLK clock is configured for a sampling rate of 8 ksp/s. Because this application only calculates the volume, a higher sample rate for better audio quality is not required. Ideally, the audio wave captured should oscillate around zero. The PDM/PCM hardware block is also configured to enable a high-pass filter. This filter attenuates low frequencies that add offset to the conversion.

The calculated volume is sent over the UART. Use a terminal program on your PC to observe the data. The code example also turns ON a kit LED when the calculated volume is greater than a predefined threshold. The threshold can be used as a noise threshold so that this example can run in noisy environments. By pressing the SW2 button, you can set a new noise threshold based on the current volume. Note that you should remove any source of sound and avoid speaking close to the microphone while pressing the button.

## Design Considerations

This code example runs on CY8CKIT-062-BLE or CY8CKIT-062 kits, which have a PSoC 6 device. To port the design to other PSoC 6 devices and kits, change the target device using PSoC Creator **Project > Device Selector**, and pin assignments in the Design Wide Resources window.

## Hardware Setup

This example requires the CY8CKIT-028-EPD shield to be connected to CY8CKIT-062 (-BLE).

## Operation

1. Connect the CY8CKIT-028-EPD shield to CY8CKIT-062.
2. Build the “CE218636\_PDM\_PCM” project and program CY8CKIT-062. For more information on building projects and device programming, see PSoC Creator Help.
3. Touch, speak, or play any sound over the microphone. Observe that the Green LED on CY8CKIT-062 turns ON.
4. If the LED is always ON or blinking, without playing any sound over the microphone, press the CY8CKIT-062 SW2 button to reset the noise threshold.
5. Open a serial terminal in the PC and connect to the COM port created by CY8CKIT-062. Configure the baud rate at 115200 bps. Observe the volume being reported in real time.

## Components

Table 1 lists the PSoC Creator Components used in this example, as well as the hardware resources used by each.

Table 1. List of PSoC Creator Components

Component	Instance Name	Hardware Resources
PDM_PCM	PDM_PCM	PDM/PCM Block
UART	UART	SCB
Interrupt	PCM_ISR	Interrupt [CM4]
Digital Output Pin	PDM_CLK	GPIO
Digital Output Pin	LED	GPIO
Digital Input Pin	PDM_DATA	GPIO
Digital Input Pin	SW2	GPIO

## Parameter Settings

This section shows the changed settings for various Components as well as the system clocks.

### PDM\_PCM

The PDM\_PCM Component is configured for a sampling rate of 8 ksps. Configure the HFC1k1 clock to a specific frequency (see below). The PDM\_CLK frequency is calculated as:

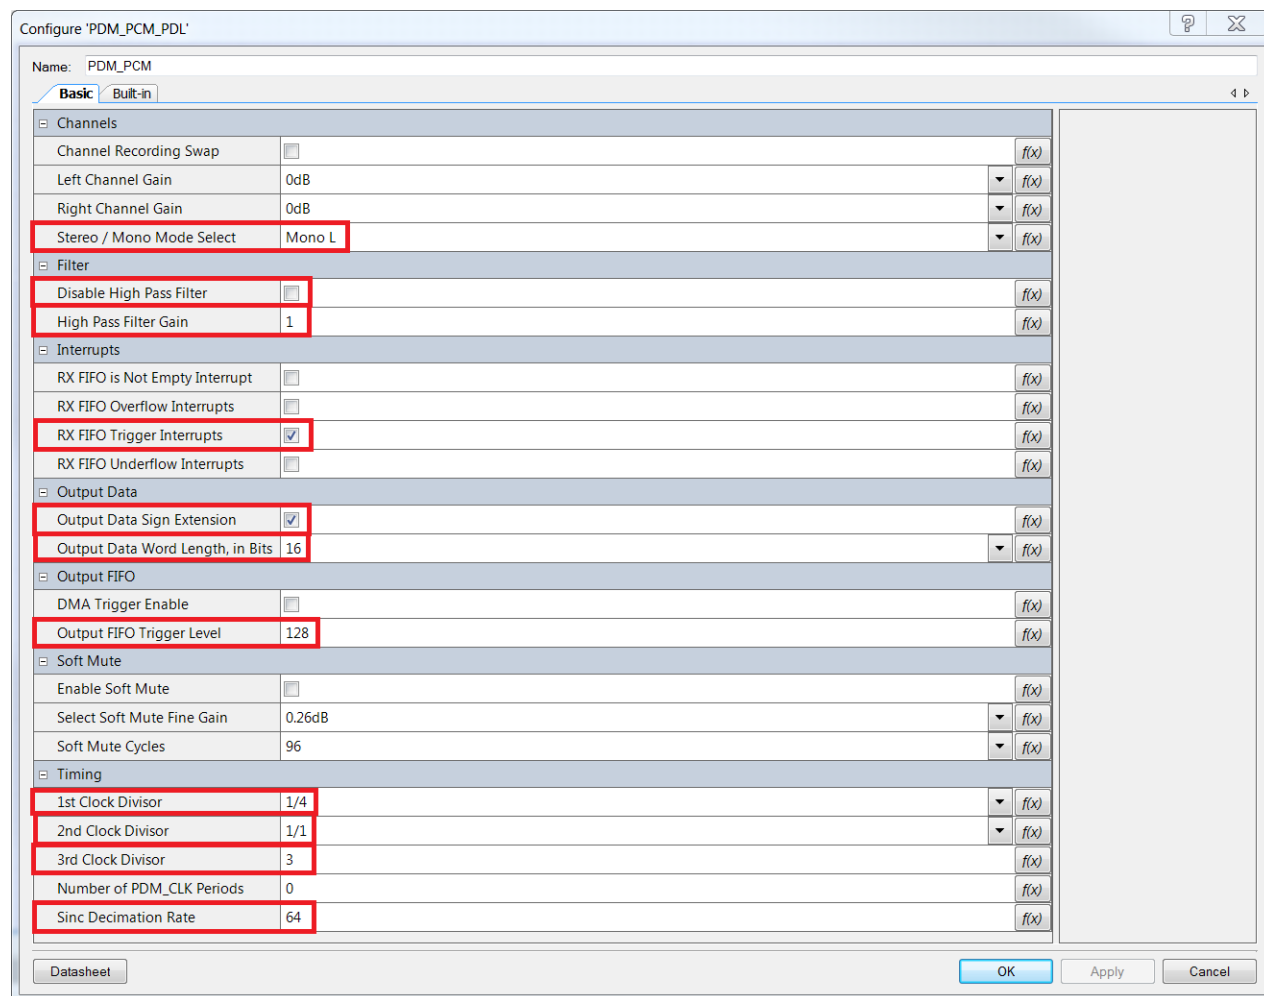

$$\text{PDM CLK (kHz)} = \frac{\text{HFC1k1 (kHz)}}{1\text{st Clock Divisor} \times 2\text{nd Clock Divisor} \times (3\text{rd Clock Divisor} + 1)}$$

The sampling rate is calculated as:

$$\text{Sampling Rate (ksps)} = \frac{\text{PDM CLK}}{2 \times \text{Sinc Decimation Rate}}$$

Figure 3 shows the PDM\_PCM Component configuration window.

Figure 3. PDM\_PCM Component Configuration Window

### PCM\_ISR

The PCM Interrupt Type is configured to be **Auto-Select Trigger**.

### UART

The UART is configured to be **TX only** and baud rate (bps) equal to **115200**.

### SW2

The pin drive mode is configured to be **Resistive Pull Up** and the Interrupt to be **Rising Edge**.

### LED

The pin drive mode is configured to be **Strong Drive** and the Initial drive state to be **High (1)**.

## Design-Wide Resources

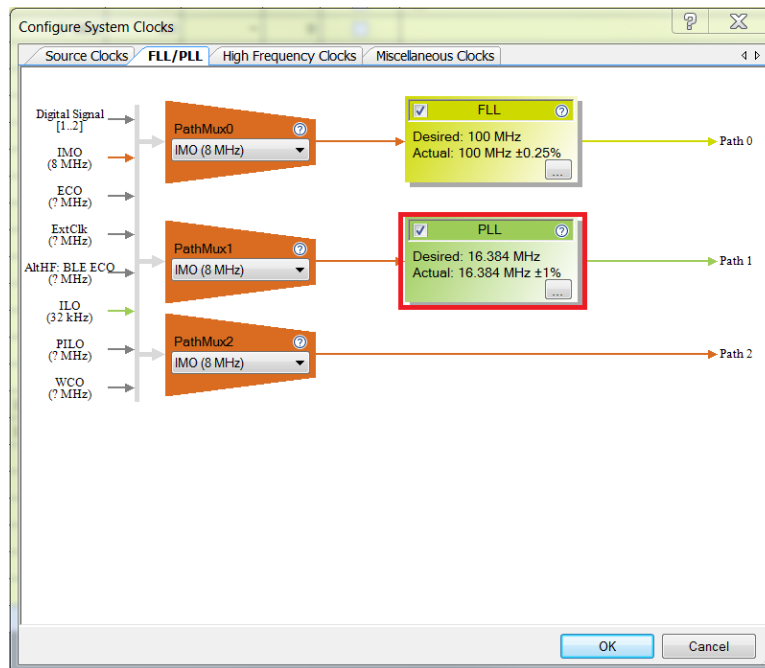

In the Configure System Clocks FLL/PLL tab, enable the PLL to be 16.384 MHz. This clock frequency comes from the following equation:

$$\text{HFClk1} = \text{Sampling Rate} \times \text{1st Clock Divisor} \times \text{2nd Clock Divisor} \times (\text{3rd Clock Divisor} + 1) \times 2 \times \text{Sinc Decimation Rate}$$

$$\text{HFClk1} = 8\text{k} \times 4 \times 1 \times (3 + 1) \times 2 \times 64 = 16.384 \text{ MHz}$$

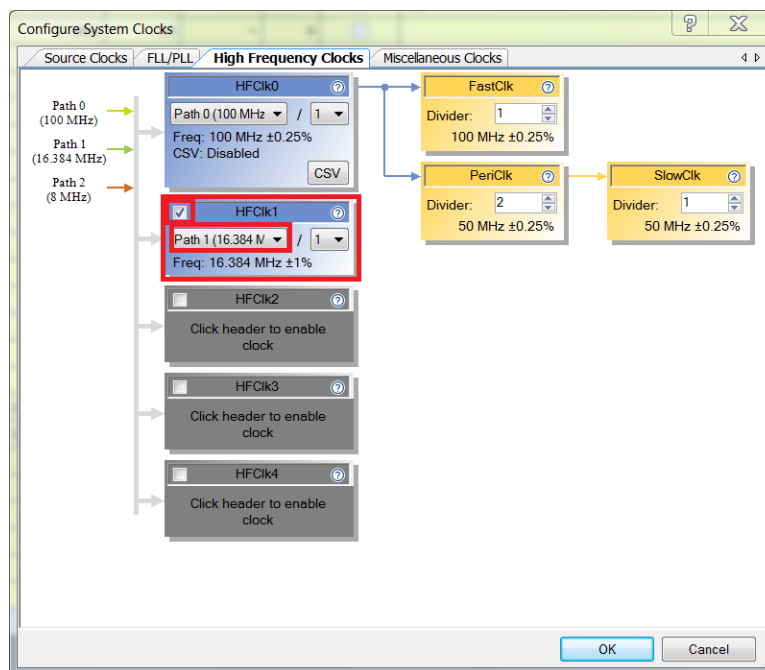

Figure 4 shows the configuration of the PLL.

Figure 4. Clock Configuration Window

Configure the High Frequency Clocks HFCIk1 to be linked to Path 1. Figure 5 shows how the high-frequency clocks are configured.

Figure 5. High Frequency Clock Configuration
